## Today's lecture

- ► Multiple Linear Regression
  - Assumptions
  - ► Interpretation

### Motivation

Most applications involve more that one covariate – if more than one thing can influence an outcome, you need multiple linear regression.

- ▶ Improved description of y|x
- ► More accurate estimates and predictions
- ► Allow testing of multiple effects
- Includes multiple predictor types

### Multiple linear regression model

▶ Observe data  $(y_i, x_{i1}, ..., x_{ip})$  for subjects 1, ..., n. Want to estimate  $\beta_0, \beta_1, ..., \beta_p$  in the model

$$y_i = \beta_0 + \beta_1 x_{i1} + \ldots + \beta_1 x_{ip} + \epsilon_i; \ \epsilon_i \stackrel{iid}{\sim} (0, \sigma^2)$$

- Assumptions (residuals have mean zero, constant variance, are independent) are as in SLR
- ▶ Impose linearity which (as in the SLR) is a big assumption
- ▶ Our primary interest will be E(y|x)
- Eventually estimate model parameters using least squares

### Multiple linear regression model

### Multiple linear regression model
